Executive Summary

CMG Financial operates in a highly regulated and competitive mortgage and financial services environment. Over time, the organization has accumulated a complex network of interconnected legacy systems, manual processes, and cross-departmental workflows. While the company continues to invest in research, product development, and operational improvements, the current request intake and prioritization process has not scaled to match organizational complexity and rising volumes of requests. Requests originate from multiple departments, often lack sufficient detail, and require extensive manual intervention by the product team. Existing dashboards and tools provide limited analytics, making it difficult to evaluate, prioritize, and sequence initiatives efficiently. As a result, high-impact requests may be delayed, low-value work may consume resources, and innovation is constrained.

Through numerous stakeholder interactions, the team identified that the core problem lies in request intake and prioritization. Product managers spend significant time cleaning and elaborating requests because requestors cannot edit submissions after entry, the one-size-fits-all form fails to capture request-specific details, and manual routing and approval processes introduce bottlenecks. Prioritization is equally challenging, with new requests being compared manually against existing backlogs, and a lack of structured evaluation frameworks delaying high-value initiatives.

The ultimate objective is to improve the quality of requests, streamline acceptance and prioritization, and reduce manual intervention through AI-assisted automation.

To address these challenges, we developed a three-pronged approach:

1. **Improve the Intake Process:** Tailored templates for each request type will ensure submissions are complete and structured, capturing all relevant details upfront. This reduces ambiguity, minimizes rework, and ensures proper routing and approvals from the start.
2. **Optimize Handling After Intake:** Workflow enhancements will automatically route requests to the correct managers and Product Owners, align work with the appropriate skill sets, and reduce unnecessary handoffs across teams. This streamlines evaluation, accelerates execution, and ensures that requests are handled efficiently.
3. **Introduce an AI/Agent Layer:** AI capabilities will categorize incoming requests, suggest priorities based on business rules and criticality, and summarize

unstructured inputs into structured fields. This reduces manual workload, accelerates decision-making, and allows the product team to focus on higher-value activities.

The business impact of these improvements is significant. Standardizing request intake and routing will reduce the product manager bottleneck, eliminate duplicated effort, and improve request quality. Optimizing workflows will increase throughput, ensure high-value work is prioritized effectively, and reduce delays caused by manual approvals. Finally, introducing AI-assisted automation will enhance scalability, accelerate delivery of enhancements and bug fixes, and enable CMG Financial to respond more quickly to evolving business needs. Collectively, these measures strengthen operational efficiency, support innovation, and reinforce CMG Financial's competitive position in a fast-evolving financial services landscape.

Problem Context

Company Background

CMG Financial is a privately held, well-established financial services organization operating primarily in the U.S. residential mortgage lending space. Over multiple decades of growth, the company has built a strong market presence through a diversified product portfolio, national lending operations, and a reputation for reliability and compliance in a highly regulated industry. CMG Financial serves a broad customer base and operates within a complex ecosystem of internal teams, external partners, regulatory bodies, and technology vendors.

As a mature organization, CMG Financial has made significant long-term investments in systems, processes, and organizational capabilities that support scale, risk management, and regulatory adherence. These investments have enabled stability and consistency, but they have also introduced structural and operational complexity. In an industry undergoing rapid digital transformation driven by evolving customer expectations, fintech innovation, and competitive pressure, this complexity presents challenges in translating insight into action at speed.

Within this context, CMG Financial continues to invest in market research, competitive analysis, user insights, and emerging technologies. However, realizing the full value of these investments increasingly depends on the organization's ability to synthesize insights, align stakeholders, and deliberately prioritize initiatives that deliver measurable business outcomes.

Overview of the Problem

Financial services organizations frequently struggle to convert research insights spanning market trends, competitive intelligence, customer behavior, and technical advancements into actionable, prioritized initiatives. While insights are generated across multiple functions, there is often no consistent, end-to-end mechanism to translate these learnings into productized solutions, clear investment decisions, or execution-ready roadmaps.

This is true for CMG Financial as they observe that their insights often remain fragmented, underutilized, or treated as isolated inputs rather than integrated drivers of strategy. Initiatives of vastly different potential impact often compete on equal footing, making it difficult to distinguish high-value opportunities from incremental or low-return efforts. This lack of clarity creates significant opportunity costs, as capital and talent are spread across initiatives without a shared understanding of expected customer value, product-level economics, or long-term strategic differentiation.

Over time, this dynamic can cause CMG Financial to default to business-as-usual execution, prioritizing known processes, legacy workflows, and historically funded initiatives over deliberate, evidence-based investment decisions. Research-driven opportunities and innovative proposals may struggle to advance, not because they lack strategic value, but because the organization lacks consistent frameworks to evaluate impact, compare trade-offs, and align stakeholders across product, technology, operations, and compliance. In an increasingly competitive mortgage and financial services landscape, this limitation in translating insight into executable, value-driven initiatives can constrain growth, slow the pace of innovation, and erode CMG Financial's ability to differentiate while maintaining its strong foundation of stability and risk management.

Current Setup

CMG Financial's current operating environment reflects the realities of a mature financial institution. The organization relies on a network of legacy systems that have evolved over time to support core lending operations, compliance requirements, and internal workflows. These systems are deeply interconnected, meaning that changes to one component often have cascading effects across multiple downstream and upstream systems.

As a result, introducing new capabilities – whether enhancements to existing systems or the adoption of new tools – requires careful coordination, extensive testing, and consideration of data dependencies and migration paths. This complexity makes rapid iteration challenging and extends the timeline for implementing changes. Even well-justified improvements can require lengthy validation and development processes before reaching production.

In addition, many operational and decision-support processes remain manually monitored, with limited end-to-end automation. There is a promising opportunity to incorporate AI and advanced analytics to improve efficiency and generate insights; however, the adoption is constrained by regulatory and compliance considerations inherent to financial services. As a result, any move toward greater automation or AI-assisted workflows requires deliberate study, risk assessment, and incremental implementation.

Together, these factors create an environment where insights are generated but not easily operationalized, change is costly and slow, and prioritization decisions lack a unified, value-based framework. Addressing these challenges requires a structured approach to synthesizing research, evaluating impact, and translating insight into executable strategy within the constraints of CMG Financial's regulatory and technical landscape.

Problem Statement

Framing the Problem

Through numerous interactions with CMG Financial stakeholders, our team narrowed the scope of the engagement to a critical operational bottleneck: request intake and prioritization within the product organization. While CMG Financial continues to receive a steady volume of requests aimed at improving systems, processes, and customer outcomes, the mechanisms for capturing, evaluating, and prioritizing these requests have not scaled in line with the organization's complexity, technical landscape, and pace of change.

The request intake process is largely manual, which is particularly challenging given CMG Financial's network of interconnected legacy systems and the diverse origins of requests across the organization. Submissions frequently lack sufficient business context, technical clarity, or articulation of expected impact, requiring extensive manual review and refinement by the product team. Limited analytical support within existing dashboards further compounds this issue, forcing prioritization decisions to rely on manual comparison across an extensive backlog, increasing subjectivity and the risk that high-impact initiatives are delayed or deprioritized.

Problem Definition

The challenges identified within CMG Financial's request management process can be articulated as two distinct but interdependent problem areas, each pointing to a clear, actionable requirement.

1. Request Input Standardization

Due to the high volume of cross-departmental requests that frequently lack sufficient business and technical detail, CMG Financial needs a standardized and scalable request intake mechanism so it can consistently capture high-quality, execution-ready requests while minimizing manual interpretation and rework by the product team.

2. Prioritization and Decision Support

Due to limited analytical support and reliance on manual comparison across new and existing requests, CMG Financial needs a structured, data-supported prioritization framework so it can efficiently evaluate relative impact, feasibility, and strategic alignment and deliberately allocate resources to the highest-value initiatives.

Approach

Our approach focused on establishing a clear, shared understanding of the end-to-end request lifecycle before attempting to identify solutions. Given the complexity of CMG Financial's operating environment, the first priority was to clarify how requests currently move through the organization so that sources of friction, ambiguity, and inefficiency could be systematically identified.

To achieve this, we spent the majority of the engagement understanding the request intake process through interviews and working sessions with members of the product team. These discussions helped surface both the formal steps and the informal workarounds involved in managing requests.

We then decomposed the full journey of a request from its point of origin through evaluation, prioritization, development, and eventual production into a series of processes. Each process was mapped step by step into a detailed flow diagram with broken links used to highlight pain points, manual interventions, and areas of breakdown within the current state.

Understanding the Input Form

Requests at CMG Financial can be initiated by any team member across any department within the organization. The primary mechanism for submitting requests is a Microsoft-based input form, which serves as the initial entry point into the product intake process. This form is designed to capture descriptive information about the request and provide the product team with baseline context for evaluation.

The form prompts requestors to answer a series of questions intended to describe the issue and its potential impact. A key input focuses on the users affected by the request, including both the estimated number of users and the type of users impacted. User types are categorized as either internal or external. Internal users typically include employees and operational stakeholders, while external users may include business-to-business partners, client organizations, or end customers. This distinction is intended to help the product team assess the scope and reach of the request.

In addition, the form asks requestors to identify the systems that may be impacted by the proposed change by choosing them from a checklist. This is a crucial input due to the complexity of the interconnected network of legacy systems. We tabulated some of the systems regularly called, the ownership of the systems whether internal or external and the teams in the company that interacted with these systems.

System	Department	Internal /external
Clear 2.0 Clear 1.0	Sales	Internal
Clear Docs	Sales Disclosures Processing	Internal
SmartApp	Sales	Internal
Home Portal	Sales	Internal
Salesforce	Sales Servicing	External
Partner Portal(3 party builders, etc)	Sales	Internal
Secure Doc Upload	Sales Processing	Internal
ALTA Admin Portal	Product - App support teams	Internal
House Canary (used for marketing) {integration with home portal}	Marketing /sales	External
IDS (doc interface)	Disclosures Closing Post closing	External
Optimal Blue	Sales Processing	External
DocuTech	Disclosures Closing Post closing	External
Byte	Sales Processing Servicing Closing Post Closing Disclosures	External

Figure: a non-exhaustive list of systems in use at CMG Financial

Requestors are also required to articulate the underlying business goal of the request, including why the work is needed, the value it is expected to deliver, and whether the request represents an efficiency improvement or a blocking issue that prevents critical work from being completed.

The form provides the ability to attach supporting artifacts such as screenshots or screen-recorded videos to help illustrate the issue which are especially relevant in cases of bugs and glitches and help reduce ambiguity during initial review.

Subcategory	Volume
Sales/Branch	463
Bug Fix	326
Access Update	131
Other	123
UI/UX	123
Condition	120
New Product	72
Workflow/Process	70
Fee Update	66
Product Update	53
JV Exclusion	37
Reporting/Data	30
General Request	25
System Integration	15
Testing/QA	13
Permission Update	12
Training/Communication	12

Figure: example of the types of requests. Note that the volumes are indicative of the active requests at the time of discussion. Exact distribution might vary from time to time.

Request Acceptance and Prioritization

Once a new request is submitted, the product manager initiates the acceptance process by updating the title to indicate the relevant platform and impacted area. They then review the description to ensure it is complete. If critical details are missing, the product manager reaches out to the requestor to gather additional information, or supplements the request with their own knowledge, including producing artifacts such as screenshots when necessary, since the requestor cannot edit the form after submission.

Next, the product manager classifies the request as either a bug or an enhancement. Bug requests are typically fast-tracked to the business analyst, who determines whether the issue requires action. Resolved or invalid bugs are closed, while actionable bugs are assigned to developers. Developers assess the scope: issues that can be resolved quickly are addressed immediately, while larger items are added to an epic for future development. Enhancement requests undergo additional verification before being presented during the biweekly prioritization call. In this meeting, new enhancements are compared against existing tickets, and priorities are reassessed for the upcoming sprint. Based on this evaluation, high-value enhancements may enter development, while lower-priority items are deferred.

Issues Identified

Through analysis of the current request intake and prioritization process, several critical issues were identified that constrain efficiency, slow delivery, and increase reliance on manual intervention:

1. Product Manager Bottleneck and Rework

Incomplete or ambiguous submissions flow directly to product managers, who must invest significant time cleaning, elaborating, and supplementing requests. Because requestors cannot edit submissions after entry, this creates a persistent rework burden.

2. Lack of Categorization

A one-size-fits-all input form is used for all request types, preventing customized data capture for bugs, enhancements, or other categories. This leads to missing information, delays in evaluation, and inconsistent request quality.

3. Missing Routing Logic

The form does not capture critical metadata such as source platform or approvers. As a result, product managers manually determine reviewers and approvers for

each request, introducing inefficiency and potential misrouting.

4. Ineffective Prioritization

Requests are not systematically sequenced against the existing backlog. New requests create additional work queues rather than integrating with ongoing priorities, and multi-step approval chains slow the progress of enhancements.

5. Volume Outpacing Capacity

Rising request volume—often exceeding ten submissions per day—outstrips the process bandwidth. Simple requests are mixed with complex ones, further straining manual review and prioritization efforts.

6. Duplicated Effort and Limited Visibility

Requestors lack real-time visibility into request status, prompting resubmissions, repeated manual descriptions, and follow-ups. Standardizable information is frequently retyped, creating unnecessary duplication of effort.

Solution Options

Overview of Solutions

Based on the challenges identified in the request intake and prioritization process, we developed a set of solutions focused on improving efficiency, reducing manual effort, and enabling data-driven decision-making. These solutions can be grouped into three primary areas:

1. Improve the Intake Process

Ensure that all requests enter the system with sufficient detail, correct routing, and the necessary approvals. By standardizing submissions and capturing the right information upfront, this approach reduces rework for the product team, minimizes delays, and mitigates compliance risk.

2. Optimize Handling After Intake (Workforce & Workflow Optimization)

Streamline the post-submission process by reducing unnecessary handoffs between teams. Requests are automatically assigned to the appropriate teams based on type and scope, and tasks are matched to the right skill sets. This ensures faster evaluation, efficient execution, and better alignment between work and organizational capabilities.

3. Introduce an Automated AI/Agent Layer

Leverage AI capabilities to enhance request processing. Incoming requests are automatically categorized based on their description, priority is suggested according to business rules and criticality, and long or unstructured descriptions are summarized into structured fields. This reduces manual effort, accelerates decision-making, and enables the product team to focus on higher-value activities.

Introduction of Multi Capability Agent

We propose to introduce MCP (Multi-Capability Processing) Agent in order to automate the intake process. We envision creating an AI-powered system designed to assist in processing and managing incoming requests with speed, accuracy, and consistency. It would leverage natural language processing and domain-specific business rules to summarize, classify, and prioritize requests while maintaining a human-in-the-loop oversight mechanism.

The strengths of the MCP Agent lie in its ability to:

- Standardize and normalize request data across teams and departments, reducing ambiguity.
- Automate repetitive and time-intensive tasks, freeing the product team to focus on high-value decisions.
- Support data-driven prioritization by evaluating requests consistently against defined business rules and historical patterns.

Multi-Step AI Process: Discrete Agents for Summarization, Classification, and Prioritization

To maximize control, scalability, and transparency, the MCP Agent workflow is modularized into discrete agents for Summarization, Classification, and Priority Scoring. The multi-step approach provides several advantages:

- **Greater control and visibility:** Each agent performs a specific task, allowing stakeholders to monitor and verify the output at each stage.
- **Modular development and deployment:** Individual agents can be released into production independently, enabling incremental adoption even if the full AI workflow is not yet complete.
- **Targeted issue identification:** If errors or inconsistencies arise, it is easier to pinpoint which stage of the workflow requires adjustment, ensuring faster debugging and continuous improvement.

In the context of the problem statement, the chain of agents addresses several key pain points:

- **Request quality and completeness:** The summarization agent ensures long or unclear descriptions are distilled into structured, actionable summaries.
- **Ineffective prioritization:** The priority scoring agent automatically evaluates impact, urgency, and affected user groups to reduce manual backlog comparison.
- **Manual categorization and routing bottlenecks:** The classification agent assigns request types and routes tickets to the appropriate Product Owner or team, reducing handoffs and delays.

AI-Powered Request Intake & Resolution Flow

To streamline request intake, prioritization, and resolution, we propose CMG Financial can implement an AI-assisted workflow that combines automation with human oversight. The following is a step by step breakdown of the workflow of the solution.

1. User Submits Ticket

Users across any department submit requests via the standardized intake form. Submissions can include detailed text descriptions, screenshots, videos, or data files. This step ensures that each request enters the system in a structured manner, providing the AI with sufficient context for accurate summarization, classification, and prioritization. Capturing rich inputs upfront reduces downstream rework and clarifications.

2. MCP Agent – Summarizer

The AI summarization agent condenses long or unstructured request descriptions into a concise 2–3 line summary. It also normalizes terminology across teams and departments, ensuring that different stakeholders interpret the request consistently. This reduces ambiguity and accelerates the review process by providing product managers with a clear, digestible version of the issue or request.

3. MCP Agent – Ticket Classifier

The AI automatically categorizes requests into predefined types such as Bug, Enhancement, Access Issue, Underwriting (UW) Blocker, Funding Blocker, or Data Issue. Classification allows the system to route tickets to the correct team or Product Owner, apply ticket-specific handling rules, and tailor prioritization criteria for each category, eliminating delays caused by manual triage.

4. MCP Agent – Priority Scorer

The AI assigns a priority level (P1–P4) based on a combination of business impact,

affected user groups, workflow stage, and historical data. High-impact or time-sensitive requests are flagged for immediate attention, while lower-priority items are sequenced appropriately. This step ensures that the organization focuses resources on initiatives that deliver the most value.

5. Automated System Actions

After classification and prioritization, the system can trigger automated operational tasks. Examples include creating tickets in Jira, sending Slack notifications to relevant stakeholders, or initiating automated remediation for simple issues using Airflow DAG workflows. This reduces manual handoffs and ensures faster response times.

6. Human-in-the-Loop Oversight

Product managers review AI-generated outputs for edge cases or ambiguous requests. They can override the AI's summary, category, or priority as needed. This combination of AI automation with human judgment ensures both efficiency and accuracy, while maintaining accountability for critical decisions.

7. Final Execution & Dashboard Reporting

Once approved, workflows are executed automatically via Airflow. A Streamlit-based dashboard provides real-time visibility into ticket status, SLAs, throughput, and trends. Leadership and product teams can monitor performance metrics, identify bottlenecks, and make data-driven decisions, ensuring transparency and continuous process improvement.

Figure: Overview of the Proposed Workflow

Recommendations for Next Steps

To realize the full benefits of the AI-powered request intake and resolution workflow, we recommend a staged approach that combines operational improvements with AI deployment. These steps ensure automation is effective, scalable, and aligned with business objectives:

1. **Finalize Request Templates and Configure Dynamic Intake Forms**

Define structured templates for each request type (e.g., Bug, Enhancement, Access Issue) and implement intake forms that adjust fields dynamically based on the request type. This ensures complete and consistent data capture at submission, reducing ambiguity and manual follow-up, while providing the AI with high-quality inputs for summarization, classification, and prioritization.

2. **Develop MCP AI Agents**

Build and train the core MCP AI agents—Summarization, Classification, and Priority Scoring—using historical request data and business rules. This step ensures that the agents are tailored to CMG Financial's processes and capable of handling real-world scenarios before integration into the workflow.

3. **Deploy MCP AI Agents in Stages**

Introduce the AI workflow incrementally: first the Summarization agent, followed by Classification, and then Priority Scoring. A modular approach allows testing and validation at each stage, reduces risk, and ensures individual components are performing correctly before full deployment.

4. **Integrate Automation with Existing Systems**

Connect AI outputs to downstream systems such as Jira, Slack, or Airflow. Automate ticket creation, notifications, and, where feasible, remediation workflows. This ensures that AI-generated insights translate into tangible operational actions.

5. **Pilot and Refine with Human-in-the-Loop Oversight**

Conduct a pilot with a controlled group of users and Product Managers to review AI-generated summaries, classifications, and priorities. Gather feedback to fine-tune models, workflows, and user interfaces. Over time, as confidence and accuracy improve, the reliance on human oversight can be gradually reduced, increasing throughput and efficiency.

6. Monitor, Measure, and Iterate

Establish dashboards and metrics to track SLA adherence, workflow efficiency, and AI performance. Use these insights to continuously refine AI agents, update templates, and optimize intake and prioritization processes over time.

Key Learnings

The challenges observed at CMG Financial—manual bottlenecks, inconsistent request intake, and ineffective prioritization—are not unique to this organization. Many Product Managers face similar issues when managing high volumes of requests, balancing strategic priorities, and operating in complex, cross-functional environments. The lessons learned from this project provide practical insights for Product Managers across industries:

1. Structured inputs are essential for efficiency.

For Product Managers, this means designing standardized intake templates and dynamic forms that capture all necessary context upfront. Doing so reduces ambiguity, minimizes manual follow-up, and allows Product Managers to focus on evaluating the impact and feasibility of requests, improving throughput and accelerating delivery of high-value initiatives.

2. Manual bottlenecks limit scalability.

Product Managers need to regularly identify points where manual effort constrains workflow, such as triage, classification, or routing. By delegating repetitive tasks and leveraging automation, Product Managers can free up capacity for strategic decision-making, ensuring the team can handle growing request volumes without delays.

3. Consistent, data-driven prioritization is critical.

Effective prioritization relies on clear criteria and structured evaluation. Product Managers should integrate quantitative insights, track dependencies, and apply transparent rules when comparing requests. This approach ensures resources are focused on initiatives with the highest impact, accelerating delivery and maximizing return on investment.

4. Modular approaches enable scalable solutions.

Breaking processes or automation into discrete, manageable stages allows incremental implementation and validation. For Product Managers, modular design makes it possible to deploy partial solutions, test assumptions, and iterate quickly,

reducing risk and providing visibility into which components contribute most to success.

5. Human oversight is necessary even with automation.

While AI and workflow tools can accelerate tasks, Product Managers must review edge cases and high-impact decisions to ensure accuracy and strategic alignment. Maintaining human judgment alongside automation improves decision quality, reduces errors, and strengthens stakeholder confidence.

6. Operational excellence is the foundation for innovation.

Before introducing AI or advanced tools, Product Managers should optimize foundational workflows—structured intake, approval routing, and standardized processes. A strong operational base ensures that automation and innovation initiatives succeed, enabling faster delivery, higher quality outputs, and continuous process improvement.

Retrospective

As the saying goes, *knowledge is power*. The first step in solving any problem is identifying it accurately. Our engagement with CMG Financial reinforced this principle: by taking a structured, investigative approach, we were able to clearly articulate the challenges within the request intake and prioritization process. Identifying the problem in its entirety across submission, triage, routing, and prioritization was crucial to developing solutions that are both practical and scalable.

Through our efforts, we illustrated the multiple levels at which the problem exists. By breaking down the workflow step by step, we brought a fresh perspective to a system that had become complex over several iterations. What appeared simple to the CMG team due to familiarity and habit was, in reality, an intricate network of interdependent processes. Highlighting these complexities helped uncover opportunities for simplification and optimization that had been overlooked.

This project also provided valuable personal learning experiences. We realized that simple charting and visualization can often be more effective than developing a full interactive prototype, especially under tight timelines. Creating clear, step-by-step flow diagrams allowed us to visually communicate the problem and its nuances efficiently, ensuring that stakeholders could quickly grasp the pain points. This reinforced the principle that clarity and impact often outweigh sophistication in early-stage problem framing.

Overall, our interactions showed how analysis, structured problem framing, and thoughtful visualization can turn hidden inefficiencies into actionable opportunities. By combining operational insights with a roadmap for AI-assisted solutions, we were able to draft a practical path to streamline workflows, reduce manual effort, and enable data-driven decision-making. This experience highlighted the importance of investigating, visualizing, and framing problems effectively before jumping into solutions, a lesson that will be invaluable for our future work as Product Managers.
